Payer Access Intelligence

Business question: which payer access differences should a Commercial Operations analyst investigate first?

Why this project

A spend dashboard shows where money moved. This analysis asks whether a product is listed, what restrictions apply, and whether a changing headline represents a real change in access. It demonstrates data harmonization, SQL analysis, Excel reporting and a Power BI semantic model.

Three findings to explain in an interview

01 BELSOMRA is listed by 277 / 367 plans (75.5%), associated with 15,253,298 members (80.5% of the observed cohort).

02 The member-weighted rate changed from 79.5% to 80.5%. Fixed August weights show no listing expansion; the headline must be interpreted with enrollment composition.

03 The review queue contains 70 plans with 3,212,054 reported members. The top two contract organizations contain 94.0% of queue enrollment; payer-document checks can begin there.

A reproducible answer, with practical limits

Independent work using public US data. No MSD affiliation or internal data is claimed.

Data and harmonization

Original CMS archives and NLM product references are downloaded and hashed. 2,244,023 formulary records become a 367-plan cohort with eight product strengths. Package records are reduced before enrollment joins. Shared formularies stay shared, missing source access stays unknown, and unkeyed enrollment rows are quarantined.

Business use

Use the Power BI report to compare brands, inspect a region and trace a strength-level difference. Use Excel to change the brand, strength view, region, snapshot and enrollment threshold. Use the investigation queue to prepare payer questions supported by exact plan and formulary identifiers.

Validation and delivery status

Delivered: source manifests, SQL marts, source audit, live-formula workbook, Power BI project and PDF report. Eight workbook scenarios passed LibreOffice Calc; 53 Power BI JSON files passed Microsoft schemas, and the model passed Microsoft TMDL parsing. Excel COM and Desktop rendering remain pending because an interactive logon session is unavailable. No Desktop-validated PBIX is claimed.
